# **Complexity Results for Confluence Problems**

Markus Lohrey

Report Nr. 1999/05

March 4, 1999

### **Abstract**

We study the complexity of the confluence problem for restricted kinds of semi-Thue systems, vector replacement systems and general trace rewriting systems. We prove that confluence for length-reducing semi-Thue systems is P-complete and that this complexity reduces to  $AC^1$  in the monadic case (where all right-hand sides consist of at most one symbol). For length-reducing vector replacement systems we prove that the confluence problem is PSPACE-complete and that the complexity reduces to NP and P, respectively, for monadic vector replacement systems and special vector replacement systems (where all right-hand sides are empty), respectively. Finally we prove that for special trace rewriting systems, confluence can be decided in polynomial time and that the extended word problem for special trace rewriting systems is undecidable.

# 1 Introduction

Rewriting systems that operate on different kinds of objects have received a lot of attention in computer science and mathematics. For all kinds of rewriting systems, confluence and termination are two of the most interesting properties. Together they guarantee the existence of unique normalforms.

Two of the most intensively studied types of rewriting systems are rewriting systems on free monoids, which are better known as semi-Thue systems [BO93], and rewriting systems on free commutative monoid, which are better known as vector replacement systems or Petri nets. Both of these types of rewriting systems may be seen as special cases of trace rewriting systems [Die90b]. Trace rewriting systems operate on free partially commutative monoids, which are in computer science better known as trace monoids. Trace monoids were introduced by [Maz77] into computer science as a model of concurrent systems.

Several decidability and undecidability results are known for the confluence problem for the different types of rewriting systems mentioned above. Let us just mention a few of these results. It is known that for length-reducing semi-Thue systems confluence can be decided in polynomial time [BO81, KKMN85]. In contrast to this result there exists a trace monoid such that confluence is undecidable for length-reducing trace rewriting systems over this trace monoid [NO88]. In [Loh98] this result was even sharpened. It was shown that unless the underlying trace monoid is free or free commutative, confluence is undecidable for length-reducing trace rewriting systems. Concerning vector replacement systems it was shown in [VRL98] that confluence is decidable but EXSPACE-hard for the class of all vector replacement systems.

In this paper we continue the investigation of the confluence problem for restricted kinds of trace rewriting systems. In Section 3 we prove that the confluence problem for length-reducing semi-Thue systems is not only solvable in polynomial time but furthermore P-complete, which roughly means that it is inherently sequential. On the other hand we prove that for the more restricted class of monadic semi-Thue systems (where monadic means that all right-hand sides consist of at most one symbol) there exists an efficient parallel algorithm (more precisely an  $AC^1$ -algorithm) that decides confluence. Concerning vector replacement systems we prove in Section 4 that for the length-reducing case, confluence is PSPACE-complete and that this complexity reduces for the monadic case and the special case (where special means that all right-hand sides are empty), respectively, to NP and P, respectively. Finally in Section 5 we prove that confluence is decidable for special trace rewriting systems in polynomial time which solves a question from [Die90b]. We end this paper by showing that in contrast to semi-Thue systems the extended word problem [BO85] is undecidable even for special trace rewriting systems that contain only one rule.

## 2 Preliminaries

In this section we will introduce some notations that we will use in this paper. Given an alphabet  $\Sigma$ ,  $\Sigma^*$  denotes the set of all finite words of elements of  $\Sigma$ . The empty word is denoted by 1. As usual  $\Sigma^+ = \Sigma^* \setminus \{1\}$ . The number of occurrences of  $a \in \Sigma$  in the word  $s$  is denoted by  $|s|_a$ . The length of the word  $s$  is denoted by  $|s|$ . The set  $\{s \in \Sigma^* \mid |s| = n\}$  is denoted by  $\Sigma^n$ . The set of all letters that occur in the word  $s$  is denoted by  $\text{alph}(s)$ . The word  $s$  written in reverse order is denoted by  $s^{rev}$ . A *context-free grammar*  $G$ , briefly CFG, is a tuple  $G = (N, \Sigma, P, S)$  where  $N$  and  $\Sigma$  are disjoint alphabets of *non-terminal symbols* and *terminal symbols*, respectively,  $P$  is the set of *productions* which is a finite subset of  $N \times (N \cup \Sigma)^*$ , and  $S \in N$  is the start symbol. A production  $(A, \alpha)$  is usually written as  $A \Rightarrow \alpha$ . Given  $A \in N$ , we denote by  $L(G, A)$  the set of all elements in  $\Sigma^*$  that can be derived by  $G$ , starting from  $A$ . Finally  $L(G) = L(G, S)$ . We say that  $G$  is *1-free* if for every production  $(A \Rightarrow \alpha) \in P$  it holds  $\alpha \neq 1$ . Let  $a_1, a_2, \dots, a_n$  be a fixed linear ordering of the alphabet  $\Sigma$ . A *commutative word* over  $\Sigma$  is a word of the form  $a_1^{e_1} a_2^{e_2} \dots a_n^{e_n}$ , where  $e_1, \dots, e_n \in \mathbb{N}$ . In particular  $1 = a_1^0 \dots a_n^0$  and  $|a_1^{e_1} \dots a_n^{e_n}| = e_1 + \dots + e_n$ . The set of all commutative words over  $\Sigma$  is denoted by  $\Sigma^\oplus$ . The concatenation of two commutative words  $a_1^{d_1} \dots a_n^{d_n}$  and  $a_1^{e_1} \dots a_n^{e_n}$  is  $a_1^{d_1+e_1} \dots a_n^{d_n+e_n}$ . In this way  $\Sigma^\oplus$  becomes isomorphic to the *free commutative monoid*  $\mathbb{N}^{|\Sigma|}$ . For a natural number  $n \in \mathbb{N}$  let  $ld(n)$  denote the logarithm of  $n$  to the base 2. Furthermore let  $bit(n) = \lfloor ld(n) \rfloor + 1$  if  $n > 0$  and  $bit(0) = 1$ , i.e.,  $bit(n)$  is the length of the binary representation of  $n$ . For  $a_1^{e_1} \dots a_n^{e_n} \in \Sigma^\oplus$  we define  $bit(s) = \sum_{i=1}^n bit(e_i)$ .

We assume that the reader is familiar with the basic notions of complexity theory, in particular with the complexity classes P, NP, and PSPACE, see for instance [Pap94]. In the following we introduce some notions concerning circuit complexity, see [BS90] for more details. All Boolean circuit that we consider in this paper are built from AND, OR, and NOT-gates. A Boolean circuit with  $n$  (linearly ordered) input nodes and exactly one output node accepts a language  $L \subseteq \{a, b\}^n$  in the obvious way. By encoding an arbitrary alphabet with more than two symbols into the alphabet  $\{a, b\}$ , a Boolean circuit can also accept a language  $L \subseteq \Sigma^n$ , where  $\Sigma$  is an arbitrary alphabet. Let  $\mathcal{F} = \{C_n \mid n \geq 0\}$  be a family of Boolean circuits, where  $C_n$  accepts a subset of  $\Sigma^n$ . We say that  $\mathcal{F}$  is *uniform* if the function  $n \mapsto C_n$  can be computed in deterministic logarithmic space. Note that this implies that there exists a polynomial  $p(n)$  such that  $C_n$  contains at most  $p(n)$  many gates. For  $k \geq 0$ ,  $AC^k$  denotes the set of all languages  $L$  such that there exists a uniform family  $\{C_n \mid n \geq 0\}$  of Boolean circuits such that the following holds: There exists a constant  $c > 0$  such that the depth of the circuit  $C_n$  (i.e. the length of the longest path from an input node to the unique output node) is at most  $c \cdot ld^k(n)$ , the fan-in (i.e. the number of inputs) of each AND and OR-gate is unbounded (but since the number of gates is bounded by a polynomial the same can be assumed for the fan-in), and finally  $C_n$  accepts the language  $\Sigma^n \cap L$ . The class  $NC^k$  is defined in the same way, but only gates of fan-in at most two are allowed. Finally  $NC = \bigcup_{k \geq 0} NC^k$ . The problems in NC are viewed as those problems that can

be efficiently parallelized. By allowing circuits with more than one output node it is possible to define classes of functions that correspond to  $AC^k$ ,  $NC^k$ , and  $NC$ . We omit the obvious formal definition, and just say that a particular function can be calculated for instance in  $AC^k$ . In particular we use reduction functions between instances of computational problems that can be calculated in  $AC^0$  and which are therefore also computable in deterministic logarithmic space by well known results, see e.g. [Pap94], Theorem 16.1. Since an AND-gate of fan-in  $m$  can be replaced by a tree of height  $ld(m)$  which consists of AND-gates of fan-in two, and similarly for OR-gates, the following hierarchy is obvious.

$$NC^0 \subseteq AC^0 \subseteq NC^1 \subseteq AC^1 \subseteq NC^2 \subseteq \dots \subseteq NC \subseteq P$$

For most of these inclusions it is unknown whether they are proper. In particular it is an open problem whether  $NC = P$ . It is generally believed that  $NC \subsetneq P$ . If this is true then problems that are  $P$ -complete under  $NC$ -reductions cannot be contained in  $NC$ , i.e., are inherently sequential.

In the following we introduce some notions from trace theory, see [DR95] for more details. An *independence alphabet* is an undirected graph  $(\Sigma, I)$ , where  $\Sigma$  is a finite alphabet and  $I \subseteq \Sigma \times \Sigma$  is an irreflexive and symmetric relation, called an *independence relation*. Given an independence alphabet  $(\Sigma, I)$  we define the *trace monoid*  $\mathbb{M}(\Sigma, I)$  as the quotient monoid  $\Sigma^* / \equiv_I$ , where  $\equiv_I$  denotes the least equivalence relation that contains all pairs of the form  $(sabt, sbat)$  for  $(a, b) \in I$  and  $s, t \in \Sigma^*$ , which is a congruence on  $\Sigma^*$ . An element of  $\mathbb{M}(\Sigma, I)$ , i.e., an equivalence class of words, is called a *trace*. The trace that contains the word  $s$  is denoted by  $[s]_I$ . The neutral element of  $\mathbb{M}(\Sigma, I)$  is the empty trace  $[1]_I$  which will be also denoted by 1. Concatenation of traces is defined by  $[s]_I [t]_I = [st]_I$ . Since for all words  $s, t \in \Sigma^*$ ,  $s \equiv_I t$  implies  $|s| = |t|$  and  $alph(s) = alph(t)$ , we can define  $|[s]_I| = |s|$  and  $alph([s]_I) = alph(s)$ . The independence relation  $I$  can be lifted to  $\mathbb{M}(\Sigma, I)$  by  $u I v$  if  $alph(u) \times alph(v) \subseteq I$ . For the rest of this section let  $(\Sigma, I)$  be an independence alphabet and let  $M = \mathbb{M}(\Sigma, I)$ . If  $I = (\Sigma \times \Sigma) \setminus Id_\Sigma$ , where  $Id_\Sigma = \{(a, a) \mid a \in \Sigma\}$ , then  $M$  is isomorphic to the free commutative monoid  $\mathbb{N}^{|\Sigma|} \simeq \Sigma^\oplus$ . On the other hand if  $I = \emptyset$  then  $M$  is isomorphic to the free monoid  $\Sigma^*$ . The following lemma is a generalization of Levi's lemma for traces [CP85], which states that for  $u_1, u_2, v_1, v_2 \in M$  it holds  $u_1 u_2 = v_1 v_2$  if and only if there exist  $w_{i,j} \in M$  ( $1 \leq i, j \leq 2$ ) such that  $u_i = w_{i,1} w_{i,2}$ ,  $v_i = w_{1,i} w_{2,i}$  ( $1 \leq i \leq 2$ ) and  $w_{1,2} I w_{2,1}$ . The following lemma can be proved by induction on  $n + m$  using Levi's lemma for the case  $n = 2 = m$ .

**Lemma 2.1.** Let  $u_1, \dots, u_m, v_1, \dots, v_n \in M$ . Then it holds

$$u_1 u_2 \dots u_m = v_1 v_2 \dots v_n$$

if and only if there exist  $w_{i,j} \in M$  ( $1 \leq i \leq m, 1 \leq j \leq n$ ) such that

- $u_i = w_{i,1} w_{i,2} \dots w_{i,n}$  for every  $1 \leq i \leq m$ ,
- $v_j = w_{1,j} w_{2,j} \dots w_{m,j}$  for every  $1 \leq j \leq n$ , and
- $w_{i,j} I w_{k,l}$  if  $1 \leq i < k \leq m$  and  $1 \leq l < j \leq n$ .

The situation in the lemma can be visualized by the diagram below, where  $n = m = 5$ . The  $i$ -th column corresponds to  $u_i$ , the  $j$ -th row corresponds to  $v_j$  and the intersection of the  $i$ -th column and the  $j$ -th row represents  $w_{i,j}$ . Furthermore  $w_{i,j}$  and  $w_{k,l}$  are independent if one of them is north-west of the other one.

$v_5$	$w_{1,5}$	$w_{2,5}$	$w_{3,5}$	$w_{4,5}$	$w_{5,5}$
$v_4$	$w_{1,4}$	$w_{2,4}$	$w_{3,4}$	$w_{4,4}$	$w_{5,4}$
$v_3$	$w_{1,3}$	$w_{2,3}$	$w_{3,3}$	$w_{4,3}$	$w_{5,3}$
$v_2$	$w_{1,2}$	$w_{2,2}$	$w_{3,2}$	$w_{4,2}$	$w_{5,2}$
$v_1$	$w_{1,1}$	$w_{2,1}$	$w_{3,1}$	$w_{4,1}$	$w_{5,1}$
	$u_1$	$u_2$	$u_3$	$u_4$	$u_5$

*Proof.* We use induction on  $m + n$ . The case  $m = 1$  or  $n = 1$  is trivial. Thus let  $m > 1$  and  $n > 1$ . Levi's lemma applied to the identity  $(u_1 \cdots u_{m-1})u_m = (v_1 \cdots v_{n-1})v_n$  gives four traces  $x, u, v$  and  $w_{m,n}$  such that

$$u_1 u_2 \cdots u_{m-1} = xv, \quad v_1 v_2 \cdots v_{n-1} = xu, \quad u_m = uw_{m,n}, \quad v_n = vw_{m,n}, \quad u I v.$$

Next we apply the induction hypothesis to the identity  $u_1 u_2 \cdots u_{m-1} = xv$ . We obtain traces  $y_1, y_2, \dots, y_{m-1}$  and  $w_{1,n}, w_{2,n}, \dots, w_{m-1,n}$  such that

$$\begin{aligned} x &= y_1 y_2 \cdots y_{m-1}, & v &= w_{1,n} w_{2,n} \cdots w_{m-1,n}, \\ u_i &= y_i w_{i,n} \quad (1 \leq i \leq m-1), & y_k I w_{i,n} & \text{ if } 1 \leq i < k \leq m-1. \end{aligned}$$

Similarly, by the induction hypothesis applied to the identity  $v_1 v_2 \cdots v_{n-1} = xu$  there exist traces  $z_1, z_2, \dots, z_{n-1}$  and  $w_{m,1}, w_{m,2}, \dots, w_{m,n-1}$  such that

$$\begin{aligned} x &= z_1 z_2 \cdots z_{n-1}, & u &= w_{m,1} w_{m,2} \cdots w_{m,n-1}, \\ v_j &= z_j w_{m,j} \quad (1 \leq j \leq n-1), & z_i I w_{m,j} & \text{ if } 1 \leq j < i \leq n-1. \end{aligned}$$

Thus  $y_1 y_2 \cdots y_{m-1} = x = z_1 z_2 \cdots z_{n-1}$ . The induction hypothesis applied to this identity gives traces  $w_{i,j}$  ( $1 \leq i \leq m-1, 1 \leq j \leq n-1$ ) such that

- $y_i = w_{i,1} w_{i,2} \cdots w_{i,n-1}$  for every  $1 \leq i \leq m-1$ ,
- $z_j = w_{1,j} w_{2,j} \cdots w_{m-1,j}$  for every  $1 \leq j \leq n-1$ , and
- $w_{i,j} I w_{k,l}$  if  $1 \leq i < k \leq m-1$  and  $1 \leq l < j \leq n-1$ .

Altogether we now obtain the following:

- $u_i = y_i w_{i,n} = w_{i,1} w_{i,2} \cdots w_{i,n-1} w_{i,n}$  for every  $1 \leq i \leq m-1$ .
- $u_m = uw_{m,n} = w_{m,1} w_{m,2} \cdots w_{m,n-1} w_{m,n}$
- $v_j = z_j w_{m,j} = w_{1,j} w_{2,j} \cdots w_{m-1,j} w_{m,j}$  for every  $1 \leq j \leq n-1$ .
- $v_n = vw_{m,n} = w_{1,n} w_{2,n} \cdots w_{m-1,n} w_{m,n}$

Finally we have to verify that  $w_{i,j} I w_{k,l}$  if  $1 \leq i < k \leq m$  and  $1 \leq l < j \leq n$ . For the case  $k < m$  and  $j < n$  this was already stated above.

- $1 \leq i < k \leq m - 1$  and  $1 \leq l < n$ : Since  $y_k I w_{i,n}$  and  $w_{k,l}$  is a factor of  $y_k$  it holds  $w_{i,n} I w_{k,l}$ .
- $1 \leq i < m$  and  $1 \leq l < j < n$ : It holds  $z_j I w_{m,l}$ . Since  $w_{i,j}$  is a factor of  $z_j$  it holds  $w_{i,j} I w_{m,l}$ .
- $1 \leq i < m$  and  $1 \leq l < n$ : Then  $w_{i,n}$  is a factor of  $v$  and  $w_{m,l}$  is a factor of  $u$ . Since  $u I v$  we have  $w_{i,n} I w_{m,l}$ .

Now we have covered all possibilities. □

A *trace rewriting system*, briefly TRS, over the trace monoid  $M$  is a non-empty finite subset of  $M \times M$ . In the rest of this section let  $\mathcal{R}$  be an arbitrary TRS over the trace monoid  $M = \mathbb{M}(\Sigma, I)$ . If  $I = \emptyset$ , i.e.,  $M \simeq \Sigma^*$ , then  $\mathcal{R}$  is also called a *semi-Thue system*, briefly STS, over  $\Sigma^*$  (see [BO93] for a detailed introduction into the theory of semi-Thue systems). On the other hand if  $I = (\Sigma \times \Sigma) \setminus Id_\Sigma$ , i.e.,  $M \simeq \mathbb{N}^{|\Sigma|}$ , then  $\mathcal{R}$  is also called a *vector replacement system*, briefly VRS, over  $\Sigma^\oplus$  (or a VRS in the dimension  $|\Sigma|$ ). An element  $(l, r) \in \mathcal{R}$  is also denoted by  $l \rightarrow r$ . The set  $\{l \mid \exists r \in M : (l, r) \in \mathcal{R}\}$  of all left-hand sides of  $\mathcal{R}$  is denoted by  $dom(\mathcal{R})$ . The set  $\{r \mid \exists l \in M : (l, r) \in \mathcal{R}\}$  of all right-hand sides of  $\mathcal{R}$  is denoted by  $ran(\mathcal{R})$ . Given  $c = (l, r) \in \mathcal{R}$  and  $s, t \in M$ , we write  $s \rightarrow_c t$  if  $s = ulv$  and  $t = urv$  for some  $u, v \in M$ . We write  $s \rightarrow_{\mathcal{R}} t$  if there exists a  $c \in \mathcal{R}$  with  $s \rightarrow_c t$ . The transitive (reflexive and transitive) closure of  $\rightarrow_{\mathcal{R}}$  is denoted by  $\rightarrow_{\mathcal{R}}^+$  ( $\rightarrow_{\mathcal{R}}^*$ ). The transitive, reflexive and symmetric closure of  $\rightarrow_{\mathcal{R}}$  is denoted by  $\leftrightarrow_{\mathcal{R}}^*$ . It is a congruence relation on  $M$ . We say that  $\mathcal{R}$  is *terminating* if there does not exist an infinite chain  $u_1 \rightarrow_{\mathcal{R}} u_2 \rightarrow_{\mathcal{R}} u_3 \rightarrow_{\mathcal{R}} \dots$  in  $M$ . We say that a pair  $(u, v) \in M \times M$  is *confluent* (with respect to  $\mathcal{R}$ ) if there exists a  $w \in M$  such that  $u \rightarrow_{\mathcal{R}}^* w$  and  $v \rightarrow_{\mathcal{R}}^* w$ . We say that  $\mathcal{R}$  is *confluent on the trace*  $u \in M$  if for all  $v_1, v_2 \in M$  with  $u \rightarrow_{\mathcal{R}}^* v_1$  and  $u \rightarrow_{\mathcal{R}}^* v_2$  there exists a  $w \in M$  with  $v_1 \rightarrow_{\mathcal{R}}^* w$  and  $v_2 \rightarrow_{\mathcal{R}}^* w$ . We say that  $\mathcal{R}$  is *confluent* if  $\mathcal{R}$  is confluent on all  $u \in M$ . We say that  $\mathcal{R}$  is *locally confluent* if for all  $u, v_1, v_2 \in M$  with  $u \rightarrow_{\mathcal{R}} v_1$  and  $u \rightarrow_{\mathcal{R}} v_2$  there exists a  $w \in M$  with  $v_1 \rightarrow_{\mathcal{R}}^* w$  and  $v_2 \rightarrow_{\mathcal{R}}^* w$ . If  $\mathcal{R}$  is terminating then by Newman's lemma [New43]  $\mathcal{R}$  is confluent if and only if  $\mathcal{R}$  is locally confluent. A trace  $u$  is *irreducible* (with respect to  $\mathcal{R}$ ) if there does not exist a  $v \in M$  with  $u \rightarrow_{\mathcal{R}} v$ . The set of all traces in  $M$  that are irreducible with respect to  $\mathcal{R}$  is denoted by  $IRR(\mathcal{R})$ . The trace  $v$  is a *normalform* of  $u$  if  $u \rightarrow_{\mathcal{R}}^* v$  and  $v \in IRR(\mathcal{R})$ . We say that  $\mathcal{R}$  is *length-reducing* if  $|l| > |r|$  for every  $(l, r) \in \mathcal{R}$ . Obviously, if  $\mathcal{R}$  is length-reducing then  $\mathcal{R}$  is also terminating. We say that  $\mathcal{R}$  is *monadic* if  $\mathcal{R}$  is length-reducing and  $ran(\mathcal{R}) \subseteq \{1\} \cup \Sigma$ . We say that  $\mathcal{R}$  is *special* if  $ran(\mathcal{R}) = \{1\}$  and  $1 \notin dom(\mathcal{R})$ . Let  $COLR(M)$  ( $COMO(M)$ ,  $COSP(M)$ ) denote the set of all confluent TRSs over  $M$  that are length-reducing (monadic, special). The *uniform word problem* for a class  $\mathcal{C}$  of TRSs over  $M$  is the following decision problem: Given a  $\mathcal{R} \in \mathcal{C}$  and two traces  $u, v \in M$ , does  $u \leftrightarrow_{\mathcal{R}}^* v$  hold?

Since we will investigate the complexity of algorithms that take a TRS as input, we have to define the length  $\|\mathcal{R}\|$  of the TRS  $\mathcal{R}$ . First assume that  $I \neq (\Sigma \times \Sigma) \setminus Id_\Sigma$ . In this case in general the best possible coding of a rule from  $\mathcal{R}$  is to simply write down words over  $\Sigma$  that represent the left- and right-hand side of the rule. Thus we define  $\|\mathcal{R}\| = \sum\{|l| + |r| \mid (l, r) \in \mathcal{R}\}$ . But if  $I = (\Sigma \times \Sigma) \setminus Id_\Sigma$ , i.e., if  $\mathcal{R}$  is a VRS over  $\Sigma^\oplus$  we can code  $\mathcal{R}$  more efficiently by using the binary notation. Therefore in this case we define  $\|\mathcal{R}\| = \sum\{bit(l) + bit(r) \mid (l, r) \in \mathcal{R}\}$ . In this paper we always assume that a TRS  $\mathcal{R}$  is represented as a string of length  $\Omega(\|\mathcal{R}\|)$  (since the different rules of  $\mathcal{R}$  must be separated by special markers, we use the  $\Omega$ -notation).

### 3 Semi-Thue systems

For terminating STSs confluence is known to be decidable [BO81]. This classical result is based on the so called *critical pairs* of a STS. Let  $\mathcal{R}$  be a STS over  $\Sigma^*$ . The set of *critical pairs*  $CP(\mathcal{R})$  is the set

$$CP(\mathcal{R}) = \{(sr_1t, r_2) \mid (l_1, r_1), (sl_1t, r_2) \in \mathcal{R}\} \cup \{(r_1u, sr_2) \mid (st, r_1), (tu, r_2) \in \mathcal{R}, t \neq 1\}.$$

Note that  $CP(\mathcal{R})$  is finite. It is well known that  $\mathcal{R}$  is locally confluent if and only if all critical pairs are confluent [NB72]. Since the last property can be decided effectively for the class of terminating STSs, confluence is decidable for this class. For length-reducing STSs, confluence can be even decided in polynomial time [BO81]. To the knowledge of the author, the best known algorithm for deciding  $COLR(\Sigma^*)$  is the  $O(\|\mathcal{R}\|^3)$  algorithm from [KKMN85]. In this section we prove that  $COLR(\Sigma^*)$  is moreover P-complete if  $|\Sigma| \geq 2$ . Thus,  $COLR(\Sigma^*)$  seems to be inherently sequential. But this situation changes for the monadic case. At the end of this section we show that  $COMO(\Sigma^*)$  is contained in  $AC^1$ .

In order to prove that  $COLR(\Sigma^*)$  is P-complete if  $|\Sigma| \geq 2$  we will first prove that the confluence problem is P-complete for the class of all STSs (without restriction on the cardinality of the underlying finite alphabet). Afterwards we will use the following lemma.

**Lemma 3.1.** Let  $k > 2$  and  $\Sigma = \{a_1, \dots, a_k\}$ . Let  $\mathcal{R}$  be a length-reducing STS over  $\Sigma$ . Let the injective morphism  $\phi : \Sigma^* \rightarrow \{a, b\}^*$  be defined by  $\phi(a_i) = aba^{i+1}b^{k-i+2}$  for  $i \in \{1, \dots, k\}$  and let  $\phi(\mathcal{R}) = \{(\phi(l), \phi(r)) \mid (l, r) \in \mathcal{R}\}$ . Then

- (1)  $\phi(\mathcal{R})$  is length-reducing and can be calculated from  $\mathcal{R}$  in  $AC^0$ .
- (2) If  $\phi(s) \rightarrow_{\phi(\mathcal{R})} u$  then  $u = \phi(t)$  and  $s \rightarrow_{\mathcal{R}} t$  for some  $t \in \Sigma$ .
- (3)  $\phi(s) \rightarrow_{\phi(\mathcal{R})} \phi(t)$  if and only if  $s \rightarrow_{\mathcal{R}} t$ .
- (4)  $\mathcal{R}$  is confluent if and only if  $\phi(\mathcal{R})$  is confluent.

*Proof.* The first statement of the lemma is obvious (note that  $|\phi(a_i)| = k+5$  for all  $i \in \{1, \dots, k\}$ ). The second statement follows from the following statement, where  $s$  and  $t$  are non-empty words:

$$\text{If } \phi(s) = u_1\phi(t)u_2 \text{ then } u_1 = \phi(v_1) \text{ and } u_2 = \phi(v_2) \text{ for some } v_1, v_2 \in \Sigma^*. \quad (1)$$

Note that this statement does not hold for  $t = 1$ . Since we need (1) only for the case that  $t \in \text{dom}(\mathcal{R})$  and since  $\mathcal{R}$  is length-reducing, the restriction  $t \neq 1$  does not matter. The if-direction from the third statement is obvious and the only if-direction follows from the second statement of the lemma and the injectivity of  $\phi$ . The if-direction of the fourth statement follows from the second statement of the lemma as follows. Let  $\phi(\mathcal{R})$  be confluent and let  $s, t, u \in \Sigma^*$  such that  $s \rightarrow_{\mathcal{R}} t$  and  $s \rightarrow_{\mathcal{R}} u$ . Thus  $\phi(s) \rightarrow_{\phi(\mathcal{R})} \phi(t)$  and  $\phi(s) \rightarrow_{\phi(\mathcal{R})} \phi(u)$ . Confluence of  $\phi(\mathcal{R})$  implies  $\phi(t) \rightarrow_{\phi(\mathcal{R})}^* w$  and  $\phi(u) \rightarrow_{\phi(\mathcal{R})}^* w$  for some  $w \in \{a, b\}^*$ . An inductive generalization of the second statement of the lemma implies  $w = \phi(v)$  and  $t \rightarrow_{\mathcal{R}}^* v$ ,  $u \rightarrow_{\mathcal{R}}^* v$  for some  $v \in \Sigma^*$ . Thus  $\mathcal{R}$  is confluent. Finally, the only if-direction of the fourth statement of the lemma follows from (1) and the following statement:

$$\text{If } \phi(s) = uv, \phi(t) = vw \text{ then } \exists x, y, z \in \Sigma^*: u = \phi(x), v = \phi(y), w = \phi(z).$$

Together with (1), this statement implies that every overlapping of two left-hand sides of  $\phi(\mathcal{R})$  results from an overlapping of two left-hand sides of  $\mathcal{R}$ . In particular if  $(s, t) \in \{a, b\}^*$  is a critical pair of  $\phi(\mathcal{R})$  then  $s = \phi(u)$ ,  $t = \phi(v)$  for some  $u, v \in \Sigma^*$  and  $(u, v)$  is a critical pair of  $\mathcal{R}$ . Thus if  $\mathcal{R}$  is confluent then  $(u, v)$  is confluent and thus also  $(s, t)$  is confluent with respect to  $\phi(\mathcal{R})$ .  $\square$

**Theorem 3.2.**  $\text{COLR}(\Sigma^*)$  is P-complete under  $\text{AC}^0$ -reductions for every finite alphabet  $\Sigma$  with  $|\Sigma| \geq 2$ .

Before we prove Theorem 3.2 we will first investigate the uniform word problem for the class of confluent and length-reducing STSs. It is known that for a confluent and length-reducing STS the word problem is decidable in polynomial time [Boo82].

**Theorem 3.3.** The uniform word problem for the class of confluent and length-reducing STS over  $\{a, b\}^*$  is P-complete under  $\text{AC}^0$ -reductions.

*Proof.* Our starting point for the proof of the theorem is the *Generic Machine Simulation Problem*, briefly GMSP, see e.g. [GHR95]. GMSP is the following decision problem.

INPUT: A deterministic Turing machine  $\mathcal{M}$ , an input word  $w$  for  $\mathcal{M}$ , and a word  $t \in \{\#\}^*$ , where  $\#$  is a new symbol which does not occur in the description of  $\mathcal{M}$ .

QUESTION: Does  $\mathcal{M}$  terminate on input  $w$  after  $\leq |t|$  steps?

It is known that GMSP is P-complete under  $\text{AC}^0$ -reductions [GHR95]. In GMSP the Turing machine  $\mathcal{M}$  is represented by its transition table. We will

(1a)	$q_f x \rightarrow q_f$	for all $x \in \Gamma$
(1b)	$x q_f \rightarrow q_f$	for all $x \in \Gamma$
(2a)	$\alpha q^{3i} \triangleleft \rightarrow \alpha b_l p^{3(i-1)} \triangleleft$	if $\delta(q, \square) = (p, b, R)$ , $1 \leq i \leq m+1$ , $\alpha \in \Sigma_l \cup \{\triangleright\}$
(2b)	$\alpha q^{3i} a_r \rightarrow \alpha b_l p^{3(i-1)}$	if $\delta(q, a) = (p, b, R)$ , $1 \leq i \leq m+1$ , $\alpha \in \Sigma_l \cup \{\triangleright\}$
(2c)	$a_l q^{3i} \triangleleft \rightarrow p^{3(i-1)} a_r b_r \triangleleft$	if $\delta(q, \square) = (p, b, L)$ , $1 \leq i \leq m+1$
(2d)	$\triangleright q^{3i} \triangleleft \rightarrow \triangleright p^{3(i-1)} \square_r b_r \triangleleft$	if $\delta(q, \square) = (p, b, L)$ , $1 \leq i \leq m+1$
(2e)	$c_l q^{3i} a_r \rightarrow p^{3(i-1)} c_r b_r$	if $\delta(q, a) = (p, b, L)$ , $1 \leq i \leq m+1$
(2f)	$\triangleright q^{3i} a_r \rightarrow \triangleright p^{3(i-1)} \square_r b_r$	if $\delta(q, a) = (p, b, L)$ , $1 \leq i \leq m+1$

Figure 1: The STS  $\mathcal{P}(\mathcal{M}, m)$ , where  $a, b, c \in \Sigma$ ,  $q \in Q \setminus \{q_f\}$ , and  $p \in Q$ .

reduce GMSP to the uniform word problem for confluent and length-reducing STSs over  $\{a, b\}^*$ . Thus let  $(\mathcal{M}, w, \#^m)$  be an instance of GMSP. Here  $\mathcal{M} = (Q, \Sigma, \square, \delta, q_0, q_f)$  is a deterministic Turing machine, where  $Q$  is the finite set of states,  $\Sigma$  is the tape alphabet,  $\square \in \Sigma$  is the blank symbol,  $\delta : Q \setminus \{q_f\} \times \Sigma \rightarrow Q \times \Sigma \times \{L, R\}$  is the total transition function,  $q_0 \in Q$  is the initial state, and  $q_f \in Q$  is the unique final state. The word  $w \in (\Sigma \setminus \{\square\})^*$  is an input for  $\mathcal{M}$ . Note that  $\mathcal{M}$  terminates if and only if it reaches the final state  $q_f$ . Let  $\Sigma_l = \{a_l \mid a \in \Sigma\}$  and  $\Sigma_r = \{a_r \mid a \in \Sigma\}$  be two disjoint copies of  $\Sigma$  with  $\Sigma_l \cap Q = \emptyset = \Sigma_r \cap Q$ . The word  $w_r$  results from  $w$  by replacing every  $a \in \Sigma$  by  $a_r$ . Let  $\triangleright$  (left-end marker) and  $\triangleleft$  (right-end marker) be additional symbols and let  $\Gamma = Q \cup \Sigma_l \cup \Sigma_r \cup \{\triangleright, \triangleleft\}$ . We define the STS  $\mathcal{P}(\mathcal{M}, m)$  over  $\Gamma^*$  by the rules of Figure 1. The rules (1a) and (1b) make  $q_f$  absorbing. The rules (2a) to (2f) simulate the machine  $\mathcal{M}$ . Note that the state symbol is represented  $3i$  times on the left-hand side and  $3(i-1)$  times on the right-hand side. This makes  $\mathcal{P}(\mathcal{M}, m)$  length-reducing. It is also easy to see that  $\mathcal{P}(\mathcal{M}, m)$  can be computed from  $\mathcal{M}$  and  $\#^m$  in  $\text{AC}^0$  (for this it is necessary that  $m$  is given in the unary representation  $\#^m$  since  $\|\mathcal{P}(\mathcal{M}, m)\|$  increases exponentially with  $\text{bit}(m)$ ).

*Claim:*  $\mathcal{P}(\mathcal{M}, m)$  is length-reducing and confluent. Furthermore  $\mathcal{M}$  terminates on input  $w$  after  $\leq m$  steps if and only if  $\triangleright q_0^{3(m+1)} w_r \triangleleft \xrightarrow{*}_{\mathcal{P}(\mathcal{M}, m)} q_f$ .

Confluence of  $\mathcal{P}(\mathcal{M}, m)$  is obvious, since only the rules (1a) and (1b) generate critical pairs. Since  $q_f$  is absorbing, these critical pairs are confluent. Now assume that  $\mathcal{M}$  does not terminate on input  $w$  after  $\leq m$  steps. By simulating  $m+1$  steps of  $\mathcal{M}$  we obtain  $\triangleright q_0^{3(m+1)} w_r \triangleleft \xrightarrow{m+1}_{\mathcal{P}(\mathcal{M}, m)} \triangleright uv \triangleleft \in \text{IRR}(\mathcal{P}(\mathcal{M}, m))$  for some  $u \in \Sigma_l^*$ ,  $v \in \Sigma_r^*$ . But then  $\triangleright q_0^{3(m+1)} w_r \triangleleft \xrightarrow{*}_{\mathcal{P}(\mathcal{M}, m)} q_f$  cannot hold since also  $q_f \in \text{IRR}(\mathcal{P}(\mathcal{M}, m))$  and  $\mathcal{P}(\mathcal{M}, m)$  is confluent. Now assume that  $\mathcal{M}$  terminates on input  $w$  after  $\leq m$  steps. Then for some  $j \geq 1$ ,  $u \in \Sigma_l^*$ , and  $v \in \Sigma_r^*$  it holds  $\triangleright q_0^{3(m+1)} w_r \triangleleft \xrightarrow{*}_{\mathcal{P}(\mathcal{M}, m)} \triangleright u q_f^{3j} v \triangleleft$ . By applying the rules (1a) and (1b), the word  $\triangleright u q_f^{3j} v \triangleleft$  can be reduced to  $q_f$ . Thus, the claim is proved.

Now consider the STS  $\phi(\mathcal{P}(\mathcal{M}, m))$  over the alphabet  $\{a, b\}$ , where  $\phi$  is the coding function from Lemma 3.1. Then  $\phi(\mathcal{P}(\mathcal{M}, m))$  is also confluent and length-reducing and can be calculated from  $\mathcal{P}(\mathcal{M}, m)$  (and hence from  $\mathcal{M}$  and

$\#^m$  in  $AC^0$ . Furthermore  $\phi(\triangleright q_0^{3(m+1)} w_r \triangleleft) \leftrightarrow_{\phi(\mathcal{P}(\mathcal{M}, m))}^* \phi(q_f)$  if and only if  $\phi(\triangleright q_0^{3(m+1)} w_r \triangleleft) \rightarrow_{\phi(\mathcal{P}(\mathcal{M}, m))}^* \phi(q_f)$  (since  $\phi(\mathcal{P}(\mathcal{M}, m))$  is confluent and  $\phi(q_f)$  irreducible with respect to  $\phi(\mathcal{P}(\mathcal{M}, m))$ ) if and only if  $\triangleright q_0^{3(m+1)} w_r \triangleleft \rightarrow_{\mathcal{P}(\mathcal{M}, m)}^* q_f$  if and only if  $\mathcal{M}$  terminates on  $w$  after  $\leq m$  steps. This proves the theorem.  $\square$

*Proof of Theorem 3.2.* As mentioned above,  $COLR(\Sigma^*)$  belongs to P. In order to prove the P-hardness of  $COLR(\Sigma^*)$  for  $|\Sigma| \geq 2$  it suffices to prove the P-hardness of  $COLR(\{a, b\}^*)$ .

Let  $(\mathcal{M}, w, \#^m)$  be an instance of GMSP and let  $n = 3(m+1) + |w| + 2$ . Let  $\Gamma$  be the alphabet from the previous proof and let  $\mathcal{P}(\mathcal{M}, m)$  be the length-reducing and confluent STS from the previous proof. Let  $A$  and  $B$  be symbols which are not in  $\Gamma$  and define the length-reducing STS  $\mathcal{R}(\mathcal{M}, w, m)$  over  $(\Gamma \cup \{A, B\})^*$  by

$$\mathcal{R}(\mathcal{M}, w, m) = \mathcal{P}(\mathcal{M}, m) \cup \{A^n B \rightarrow \triangleright q_0^{3(m+1)} w_r \triangleleft, AB \rightarrow q_f\}.$$

With the rule  $A^n B \rightarrow \triangleright q_0^{3(m+1)} w_r \triangleleft$  we generate an initial configuration for  $\mathcal{M}$ . Since the initial state  $q_0$  is represented  $3(m+1)$  times in the initial configuration, at most  $m+1$  steps of  $\mathcal{M}$  will be simulated with the rules (2a) to (2f). Of course also  $\mathcal{R}(\mathcal{M}, w, m)$  can be computed from  $\mathcal{M}, w$ , and  $\#^m$  in  $AC^0$ .

By the claim from the proof of Theorem 3.3 the machine  $\mathcal{M}$  terminates on input  $w$  after  $\leq m$  steps if and only if  $\triangleright q_0^{3(m+1)} w_r \triangleleft \rightarrow_{\mathcal{P}(\mathcal{M}, m)}^* q_f$  which clearly holds if and only if  $\triangleright q_0^{3(m+1)} w_r \triangleleft \rightarrow_{\mathcal{R}(\mathcal{M}, w, m)}^* q_f$ .

*Claim :*  $\mathcal{R}(\mathcal{M}, w, m)$  is confluent if and only if  $\triangleright q_0^{3(m+1)} w_r \triangleleft \rightarrow_{\mathcal{R}(\mathcal{M}, w, m)}^* q_f$ .  
First assume that  $\mathcal{R}(\mathcal{M}, w, m)$  is confluent. Since

$$A^n B \rightarrow_{\mathcal{R}(\mathcal{M}, w, m)} A^{n-1} q_f \rightarrow_{(1b)}^{n-1} q_f \quad \text{and} \quad A^n B \rightarrow_{\mathcal{R}(\mathcal{M}, w, m)} \triangleright q_0^{3(m+1)} w_r \triangleleft$$

and since  $q_f \in IRR(\mathcal{R}(\mathcal{M}, w, m))$  it must hold  $\triangleright q_0^{3(m+1)} w_r \triangleleft \rightarrow_{\mathcal{R}(\mathcal{M}, w, m)}^* q_f$ . Now assume that  $\triangleright q_0^{3(m+1)} w_r \triangleleft \rightarrow_{\mathcal{R}(\mathcal{M}, w, m)}^* q_f$  holds. Then the critical pair  $(A^{n-1} q_f, \triangleright q_0^{3(m+1)} w_r \triangleleft)$  is confluent. In all other critical pairs one of the rules (1a) or (1b) must be involved. Since  $q_f$  is absorbing these critical pairs are also confluent. This proves the claim.

Now consider the STS  $\phi(\mathcal{R}(\mathcal{M}, w, m))$ , where  $\phi$  is the coding function from Lemma 3.1. Then  $\phi(\mathcal{R}(\mathcal{M}, w, m))$  is confluent if and only if  $\mathcal{R}(\mathcal{M}, w, m)$  is confluent if and only if  $\triangleright q_0^{3(m+1)} w_r \triangleleft \rightarrow_{\mathcal{R}(\mathcal{M}, w, m)}^* q_f$  if and only if  $\mathcal{M}$  terminates on input  $w$  after  $\leq m$  steps.  $\square$

In the rest of this section we will show that Theorem 3.2 does not hold any longer for monadic STSs unless  $NC = P$ . More precisely, we prove that  $COMO(\Sigma^*)$  is contained in  $AC^1$ . To the knowledge of the author this result was never stated explicitly, but it easily follows from known results. We start with the *uniform word problem for 1-free CFGs* which is the following problem:

INPUT: A 1-free CFG  $G$  over a terminal alphabet  $\Sigma$  and a word  $s \in \Sigma^*$ .

QUESTION: Is  $s \in L(G)$  ?

The following result was implicitly proven in [Ruz80], see also [GHR95], pp. 176.

**Lemma 3.4.** The uniform word problem for 1-free CFGs is in  $AC^1$ .

In [BJW82] it was shown that the question whether a pair  $(s, t)$  of words is confluent with respect to a monadic STS can be reduced to the word problem for CFGs. We present the construction from [BJW82] for completeness and in order to convince the reader that it can be carried out in  $AC^0$ . Let  $\mathcal{R}$  be a monadic STS over  $\Sigma^*$ . With  $\mathcal{R}$  we associate a 1-free CFG  $G_{\mathcal{R}}$  in the following way. Let  $\Sigma_l = \{a_l \mid a \in \Sigma\}$  and  $\Sigma_r = \{a_r \mid a \in \Sigma\}$  be two disjoint copies of  $\Sigma$  and let  $\#$  be an additional symbol. For a word  $s \in \Sigma^*$ ,  $s_l$  and  $s_r$  are defined in the obvious way. Then  $G_{\mathcal{R}} = (\Sigma_l \cup \Sigma_r \cup \{S, S_l, S_r\}, \Sigma \cup \{\#\}, P, S)$ , where  $P$  contains all productions of the form

$$\begin{aligned} S &\Rightarrow a_l S a_r \mid S S_r \mid S_l S \mid \# \text{ for } a \in \Sigma, & a_l &\Rightarrow a, & a_r &\Rightarrow a \text{ for } a \in \Sigma \\ S_l &\Rightarrow s_l, & S_r &\Rightarrow s_r^{rev} \text{ for } (s, 1) \in \mathcal{R}, & a_l &\Rightarrow s_l, & a_r &\Rightarrow s_r^{rev} \text{ for } a \in \Sigma, (s, a) \in \mathcal{R}, \\ x &\Rightarrow S_l x \mid x S_l \text{ for } x \in \Sigma_l \cup \{S_l\}, & x &\Rightarrow S_r x \mid x S_r \text{ for } x \in \Sigma_r \cup \{S_r\}. \end{aligned}$$

Obviously,  $G_{\mathcal{R}}$  can be constructed from  $\mathcal{R}$  by an  $AC^0$ -circuit. Furthermore  $L(G_{\mathcal{R}}, S_l) = \{s \in \Sigma^+ \mid s \rightarrow_{\mathcal{R}}^* 1\}$ ,  $L(G_{\mathcal{R}}, a_l) = \{s \in \Sigma^* \mid s \rightarrow_{\mathcal{R}}^* a\}$  and  $L(G_{\mathcal{R}}, S_r) = \{s \in \Sigma^+ \mid s^{rev} \rightarrow_{\mathcal{R}}^* 1\}$ ,  $L(G_{\mathcal{R}}, a_r) = \{s \in \Sigma^* \mid s^{rev} \rightarrow_{\mathcal{R}}^* a\}$ . Thus

$$L(G_{\mathcal{R}}) = \{s \# t^{rev} \mid s \rightarrow_{\mathcal{R}}^* u \text{ and } t \rightarrow_{\mathcal{R}}^* u \text{ for some } u \in \Sigma^*\}.$$

Now the following theorem is easy to prove.

**Theorem 3.5.**  $COMO(\Sigma^*)$  is in  $AC^1$ .

*Proof.* Let  $\mathcal{R}$  be a monadic STS over  $\Sigma^*$ . First we construct an  $AC^0$ -circuit that calculates from  $\mathcal{R}$  the set of all critical pairs. This is possible, since in parallel we can test for each pair of rules  $l_1 \rightarrow r_1$  and  $l_2 \rightarrow r_2$  and for each factorization  $l_1 = st$  with  $t \neq 1$  whether  $l_2$  is a prefix of  $t$  or  $t$  is a prefix of  $l_2$  (using unbounded fan-in this is clearly possible in constant depth). If this is the case, we obtain a critical pair. In a second step we have to test in parallel whether each critical pair  $(s, t) \in CP(\mathcal{R})$  is confluent. For this we construct in  $AC^0$  from  $\mathcal{R}$  the 1-free CFG  $G_{\mathcal{R}}$  and test whether  $s \# t^{rev} \in L(G_{\mathcal{R}})$  which can be done in  $AC^1$  by Lemma 3.4.  $\square$

## 4 Vector replacement systems

In [VRL98] it was shown that confluence is decidable but EXSPACE-hard for the class of all vector replacement systems. Based on critical pairs, more feasible upper bounds can be obtained for the length-reducing case. Similarly to STSs, also VRSs yield finite sets of critical pairs [BL81]. Let  $\mathcal{R}$  be a VRS over  $\Sigma^{\oplus}$ . The set  $CP(\mathcal{R})$  of critical pairs of  $\mathcal{R}$  contains exactly all pairs  $(s, t) \in \Sigma^{\oplus} \times \Sigma^{\oplus}$  such that there exist rules  $(k, p), (l, r) \in \mathcal{R}$  such that for all  $a \in \Sigma$  it holds  $|s|_a = \max(|k|_a, |l|_a) - |k|_a + |p|_a$  and  $|t|_a = \max(|k|_a, |l|_a) - |l|_a + |r|_a$ . Then  $\mathcal{R}$

is locally confluent if and only if all critical pairs are confluent. Note that there are at most  $|\mathcal{R}| \cdot (|\mathcal{R}| - 1)$  many critical pairs that are not trivially confluent. For the length-reducing case, testing all critical pairs for confluence leads to a straight-forward PSPACE-algorithm for deciding confluence. In this section we will prove that confluence is moreover PSPACE-complete for the class of all VRSs (without restriction on the dimension), i.e.,  $\bigcup_{k>0} \text{COLR}(\mathbb{N}^k)$  is PSPACE-complete. Note that the calculation of a normalform of a  $s \in \Sigma^\oplus$  with respect to a length-reducing VRS may involve a number of steps that is exponential in  $\text{bit}(s)$ . Therefore the calculation of normalforms for the finitely many critical pairs does not lead to a polynomial time algorithm (as it is the case for STSs).

**Theorem 4.1.**  $\bigcup_{k>0} \text{COLR}(\mathbb{N}^k)$  is PSPACE-complete.

*Proof.* The following problem is known to be PSPACE-complete [Kar72]:

INPUT: A *deterministic linear bounded automaton*  $\mathcal{M}$  and an input  $w$  for  $\mathcal{M}$ .

QUESTION: Does  $\mathcal{M}$  accept  $w$  ?

Let us fix a deterministic linear bounded automaton  $\mathcal{M} = (Q, \Sigma, \triangleright, \triangleleft, \delta, q_0, q_f)$  and an input  $w \in (\Sigma \setminus \{\triangleright, \triangleleft\})^*$  for  $\mathcal{M}$ , where  $Q$  is the finite set of states,  $\Sigma$  is the tape alphabet,  $\triangleright \in \Sigma$  is the left-end marker,  $\triangleleft \in \Sigma$  is the right-end marker,  $\delta : (Q \setminus \{q_f\}) \times \Sigma \rightarrow Q \times \Sigma \times \{L, R\}$  is the transition function,  $q_0 \in Q$  is the initial state, and  $q_f$  is the unique final state. The transition function must be defined such that

- the read-write head never moves to the left (right) of  $\triangleright$  ( $\triangleleft$ ) and
- does not overwrite  $\triangleright$  ( $\triangleleft$ ) by a symbol different from  $\triangleright$  ( $\triangleleft$ ) and
- does not overwrite a tape symbol  $a \in \Sigma \setminus \{\triangleright, \triangleleft\}$  by  $\triangleright$  or  $\triangleleft$ .

We identify each tape cell of  $\mathcal{M}$  with a number from  $\{0, \dots, |w| + 1\}$ , where cell 0 always contains the left-end marker  $\triangleright$  and cell  $|w| + 1$  always contains the right-end marker  $\triangleleft$ . We assume that  $\mathcal{M}$  starts with the read-write head scanning cell 0. Note that  $\mathcal{M}$  accepts  $w$  if and only if it terminates on  $w$  if and only if it reaches the final state  $q_f$ . Furthermore we may assume that the read-write head is always in cell 0 if the final state  $q_f$  is reached.

We will construct a VRS  $\mathcal{R}(\mathcal{M}, w)$  such that  $\mathcal{R}(\mathcal{M}, w)$  is confluent if and only if  $\mathcal{M}$  accepts the input  $w$ , which proves the theorem. Our construction is based on the simulation of a linear bounded automaton by a Petri net from [JLL77]. Let us define the alphabet  $\Gamma$  by

$$\Gamma = (\{0, \dots, |w| + 1\} \times Q) \cup (\{0, \dots, |w| + 1\} \times \Sigma) \cup \{A, \$\}.$$

Note that we consider pairs  $(i, q) \in \{0, \dots, |w| + 1\} \times Q$  and pairs  $(i, a) \in \{0, \dots, |w| + 1\} \times \Sigma$  as single symbols. The symbol  $(i, q)$  means that  $\mathcal{M}$  is in the state  $q$  and the read-write head is scanning cell  $i$ , whereas the symbol  $(i, a)$  means that cell  $i$  contains the tape symbol  $a$ . Since cell 0 always contains  $\triangleright$  and cell  $|w| + 1$  always contains  $\triangleleft$ , the symbols  $(0, \triangleright)$  and  $(|w| + 1, \triangleleft)$  will be always

(1a)	$\$(i, q)(i, a) \rightarrow (i + 1, p)(i, b)$	if $\delta(q, a) = (p, b, R), q \neq q_f, i \leq  w $
(1b)	$\$(i, q)(i, a) \rightarrow (i - 1, p)(i, b)$	if $\delta(q, a) = (p, b, L), q \neq q_f, i \geq 1$
(2)	$(0, q_f)x \rightarrow (0, q_f)$	if $x \in \Gamma$
(3a)	$(i, a)(i, b) \rightarrow (0, q_f)$	
(3b)	$(i, p)(j, q) \rightarrow (0, q_f)$	
(4a)	$A^n \rightarrow \$^m(0, q_0)(0, \triangleright)(1, a_1) \cdots ( w , a_{ w })( w  + 1, \triangleleft)$	
(4b)	$A^2 \rightarrow (0, q_f)$	

Figure 2: The VRS  $\mathcal{R}(\mathcal{M}, w)$ , where  $p, q \in Q$ ,  $0 \leq i, j \leq |w| + 1$ , and  $a, b \in \Sigma$ .

present. Moreover since we assumed that  $\mathcal{M}$  terminates if and only if it reaches the final state  $q_f$  and the read–write head is in cell 0, the presence of the symbol  $(0, q_f)$  indicates that  $\mathcal{M}$  has terminated. The VRS  $\mathcal{R}(\mathcal{M}, w)$  over  $\Gamma^\oplus$  is shown in Figure 2, where we assume that  $w = a_1 a_2 \cdots a_{|w|}$  and  $m = |Q| \cdot |\Gamma|^{|w|} \cdot (|w| + 2)$  and  $n = m + |w| + 4$  (we did not fix a linear ordering on  $\Gamma$ , which is necessary for  $\Gamma^\oplus$ , but this can be done in an arbitrary way).

The rules (1a) and (1b) simulate  $\mathcal{M}$  where the additional  $\$$  on the left–hand side is necessary in order to make these rules length–reducing. Rule (2) makes  $(0, q_f)$  absorbing. With the rules (3a) and (3b) it is possible to resolve critical pairs that result from the rules (1a) and (1b). In particular it is easy to see that the VRS that consists of the rules (1a), (1b), (2), (3a) and (3b) is confluent. With the rules (4a) and (4b) we intentionally create a critical pair. The first rule (4a) produces the encoding of the initial configuration of  $\mathcal{M}$ . Since each simulation step of  $\mathcal{R}(\mathcal{M}, w)$  consumes a  $\$$ , we have to make enough  $\$$ 's available for the initial configuration. Since there are at most  $m = |Q| \cdot |\Gamma|^{|w|} \cdot (|w| + 2)$  different configurations for  $\mathcal{M}$ , the automaton  $\mathcal{M}$  either terminates after  $\leq m$  steps or loops forever. Thus  $m$  many  $\$$ 's suffice. Note that in the binary representation of  $\mathcal{R}(\mathcal{M}, w)$  the  $m$  many  $\$$ 's are represented by  $O(\text{ld}(m)) = O(\text{ld}(|Q|) + |w| \cdot \text{ld}(|\Gamma|) + \text{ld}(|w| + 2))$  many bits, which is polynomial in  $|w|$  and the length of the description of  $\mathcal{M}$ . The same holds also for the number  $n = m + |w| + 4$  in the left–hand side of rule (4a) which is chosen such that (4a) is length–reducing. Finally rule (4b) writes the absorbing symbol  $(0, q_f)$ .

The proof that  $\mathcal{R}(\mathcal{M}, w)$  is confluent if and only if  $\mathcal{M}$  accepts  $w$  is similar to the proof of Theorem 3.2. First note that  $A^n \xrightarrow{(4b)} A^{n-2}(0, q_f) \xrightarrow{\binom{n-2}{2}} (0, q_f) \in \text{IRR}(\mathcal{R}(\mathcal{M}, w))$  and  $A^n \xrightarrow{(4a)} \$^m(0, q_0)(0, \triangleright)(1, a_1) \cdots (|w|, a_{|w|})(|w| + 1, \triangleleft)$ . If  $\mathcal{M}$  does not accept  $w$ , i.e., if  $\mathcal{M}$  does not terminate on input  $w$ , then by simulating  $m$  steps of  $\mathcal{M}$  we obtain

$$\begin{aligned} \$^m(0, q_0)(0, \triangleright)(1, a_1) \cdots (|w|, a_{|w|})(|w| + 1, \triangleleft) &\xrightarrow{\mathcal{R}(\mathcal{M}, w)} \\ (i, q)(0, \triangleright)(1, b_1) \cdots (|w|, b_{|w|})(|w| + 1, \triangleleft) &\in \text{IRR}(\mathcal{R}(\mathcal{M}, w)) \end{aligned}$$

for some  $i \in \{0, \dots, |w| + 1\}$ ,  $q \in Q \setminus \{q_f\}$ , and  $b_j \in \Sigma \setminus \{\triangleright, \triangleleft\}$  ( $1 \leq j \leq |w|$ ). Thus  $\mathcal{R}(\mathcal{M}, w)$  is not confluent. On the other hand if  $\mathcal{M}$  accepts  $w$ , then  $\mathcal{M}$

reaches after  $k \leq m$  steps the final state  $q_f$  and terminates in cell 0. Hence

$$\begin{aligned} & \$^m(0, q_0)(0, \triangleright)(1, a_1) \cdots (|w|, a_{|w|})(|w| + 1, \triangleleft) \rightarrow_{\mathcal{R}(\mathcal{M}, w)}^k \\ & \quad \$^{m-k}(0, q_f)(0, \triangleright)(1, b_1) \cdots (|w|, b_{|w|})(|w| + 1, \triangleleft) \rightarrow_{(2)}^+ (0, q_f). \end{aligned}$$

Since all other critical pairs of  $\mathcal{R}(\mathcal{M}, w)$  are confluent,  $\mathcal{R}(\mathcal{M}, w)$  is confluent.  $\square$

One might ask whether confluence is also PSPACE-complete for VRSs in a sufficiently large but fixed dimension. The usual technique of coding several symbols into two symbols that we applied for STSs does not work for VRSs. On the other hand there exists a simulation of a 3-counter machine with exponentially bounded counters (for which the acceptance problem is PSPACE-complete) by a VRS in the dimension 6 [Huy85]. But in this simulation unwanted critical pairs arise and it does not seem to be obvious whether these critical pairs can be resolved by adding a polynomial number of additional rules (like the rules (3a) and (3b) in the previous proof).

The following theorem follows easily from the previous proof by using the same arguments that we applied for the proof of Theorem 3.3.

**Theorem 4.2.** The uniform word problem for length-reducing and confluent VRSs is PSPACE-complete.

Similarly to the semi-Thue case, also for VRSs the complexity of the confluence problem decreases for the monadic case. This is the content of the next theorem.

**Theorem 4.3.**  $\bigcup_{k>0} \text{COMO}(\mathbb{N}^k)$  is in NP.

*Proof.* The theorem follows easily from the results of [Huy83, Esp97], which state that the *reachability problem for communication-free Petri nets* is in NP (in fact it is NP-complete). In terms of VRSs, a VRS  $\mathcal{R}$  is communication-free, if for each left-hand side  $l \in \text{dom}(\mathcal{R})$  it holds  $|l| = 1$ . Using this result, we can decide  $\bigcup_{k>0} \text{COMO}(\mathbb{N}^k)$  in NP as follows. Given a monadic VRS  $\mathcal{R}$  over  $\Sigma^\oplus$  we first construct the set of all critical pairs, as defined at the beginning of this section. Let  $(s, t) \in \Sigma^\oplus \times \Sigma^\oplus$  be one of these critical pairs. We now guess a  $u \in \Sigma^\oplus$  with  $|u| \leq |s|$  and  $|u| \leq |t|$ . It suffices to check in NP whether  $s \rightarrow_{\mathcal{R}}^* u$  and  $t \rightarrow_{\mathcal{R}}^* u$ . In order to verify whether  $s \rightarrow_{\mathcal{R}}^* u$  we proceed as follows. Let  $\mathcal{P}$  be the following communication-free VRS over  $(\Sigma \cup \{\$\})^\oplus$ , where  $\$ \notin \Sigma$  is a new symbol:

$$\mathcal{P} = \{(r, l) \mid (l, r) \in \mathcal{R}, |r| = 1\} \cup \{(\$, l) \mid (l, 1) \in \mathcal{R}\}$$

Then  $s \rightarrow_{\mathcal{R}}^* u$  if and only if  $u\$^i \rightarrow_{\mathcal{P}}^* s$  for some  $0 \leq i \leq |s| - |u|$ . Thus we simply have to guess such a number  $i$  (note that  $\text{bit}(i)$  is bounded by a polynomial in  $\text{bit}(s)$ ) and check whether  $u\$^i \rightarrow_{\mathcal{P}}^* s$ , which is possible in NP by the results mentioned above. This concludes the proof.  $\square$

Whether  $\bigcup_{k>0} \text{COMO}(\mathbb{N}^k)$  is also NP-complete is left as an open question. If we further restrict the input to be a special VRS, then we can even give a simple deterministic polynomial time algorithm that decides confluence.

**Theorem 4.4.**  $\bigcup_{k>0} \text{COSP}(\mathbb{N}^k)$  is in P.

*Proof.* Let  $\mathcal{R}$  be a special VRS over  $\Sigma^\oplus$ , where  $\Sigma = \{a_1, \dots, a_n\}$ . In order to check whether  $\mathcal{R}$  is confluent it suffices to calculate for each critical pair  $(s, t) \in \Sigma^\oplus \times \Sigma^\oplus$  normalforms of  $s$  and  $t$  and to check whether these normalforms are equal. Thus we have to prove that a normalform of a  $s \in \Sigma^\oplus$  can be calculated in P. Let  $l_1, \dots, l_m$  be the left-hand sides of  $\mathcal{R}$ . Let  $s_0 = s$  and for  $1 \leq i \leq m$  let  $s_i$  be a normalform of  $s_{i-1}$  with respect to the special one-rule VRS  $\{l_i \rightarrow 1\}$ . Then it is easy to see that  $s_m$  is a normalform of  $s$ . Thus we have to show that the normalform of  $a_1^{d_1} \cdots a_n^{d_n} \in \Sigma^\oplus$  with respect to a rule  $a_1^{e_1} \cdots a_n^{e_n} \rightarrow 1$  can be calculated in P. But this is easy. For each  $1 \leq i \leq n$  we have to calculate the integer-quotient  $q_i = \lfloor d_i/e_i \rfloor$  and take the minimum  $q = \min\{q_1, \dots, q_n\}$  of these quotients. For  $1 \leq i \leq n$  let  $f_i = d_i - q \cdot e_i$ . Then the normalform is  $a_1^{f_1} \cdots a_n^{f_n}$ .  $\square$

Also the problem whether  $\bigcup_{k>0} \text{COSP}(\mathbb{N}^k)$  is P-complete must be left as an open question.

## 5 Special trace rewriting systems

In contrast to the decidability results of the last two sections, there exists a trace monoid  $M$  such that  $\text{COLR}(M)$  is undecidable [NO88]. This result was sharpened in [Loh98], where it was shown that  $\text{COLR}(M)$  is decidable if and only if  $M$  is a free monoid or a free commutative monoid. In particular this implies that in general TRSs cannot have finitely many critical pairs (in contrast to STSs and VRSs). Furthermore these undecidability results lead to the question whether there exist restricted but non trivial classes of (length-reducing) TRSs for which confluence is decidable. In particular, in [Die90b] it was asked whether confluence is decidable for special TRSs and monadic TRSs, respectively. For the special case we answer this question positively in this section. In fact we will prove that confluence is decidable for a broader class of TRSs that satisfy the following condition, which we call condition (A): A TRS  $\mathcal{R}$  over  $\mathbb{M}(\Sigma, I)$  satisfies condition (A) if

- (1) for all  $(l_1, r_1), (l_2, r_2) \in \mathcal{R}$  and all factorizations  $l_1 = p_1 q_1$ ,  $l_2 = p_2 q_2$  with  $p_i \neq 1 \neq q_i$  for  $i \in \{1, 2\}$ ,  $p_1 I p_2$ , and  $q_1 I q_2$  it holds: There exist factorizations  $r_1 = s_1 t_1$ ,  $r_2 = s_2 t_2$  such that  $a I p_i$  implies  $a I s_i$  and  $a I q_i$  implies  $a I t_i$  for all  $a \in \Sigma$ ,  $i \in \{1, 2\}$ .
- (2) for all  $(l_1, r_1), (l_2, r_2) \in \mathcal{R}$  and all factorizations  $l_1 = p_1 s q_1$ ,  $l_2 = p_2 s q_2$  with  $s \neq 1$ ,  $p_1 I p_2$ , and  $q_1 I q_2$  it holds:  $a I s$  implies  $a r_1 = r_1 a$  and  $a r_2 = r_2 a$  for all  $a \in \Sigma$ .

```

Input: A length-reducing TRS  $\mathcal{R}$  over  $\mathbb{M}(\Sigma, I)$  that satisfies condition (A)
begin
  forall  $((l_1, r_1), (l_2, r_2)) \in \mathcal{R} \times \mathcal{R}$  do
    forall factorizations  $l_1 = p_1 s q_1, l_2 = p_2 s q_2$  with
       $s \neq 1, p_1 I p_2, q_1 I q_2$  do
         $nf_1 := NF(p_1 r_2 q_1, \mathcal{R}); nf_2 := NF(p_2 r_1 q_2, \mathcal{R});$ 
        if  $nf_1 \neq nf_2$  then
          (*) return “ $\mathcal{R}$  not confluent”
        else
           $u := nf_1 (= nf_2);$ 
          forall  $a \in \Sigma$  with  $a I p_2 s q_1$  or  $a I p_1 s q_2$  do
             $nf_1 := NF(au, \mathcal{R}); nf_2 := NF(ua, \mathcal{R});$ 
            if  $nf_1 \neq nf_2$  then
              (**) return “ $\mathcal{R}$  not confluent”
            endif
          endfor
        endif
      endfor
    endif
  (***) return “ $\mathcal{R}$  confluent”
end

```

Figure 3: The algorithm CONFL

Note that condition (A2) implies that for every rule  $(l, r) \in \mathcal{R}$  if  $a I l$  then  $ar = ra$ .

**Theorem 5.1.** The following problem is decidable for every trace monoid  $M$ :  
**INPUT:** A length-reducing TRS  $\mathcal{R}$  over  $M$  that satisfies condition (A).  
**QUESTION:** Is  $\mathcal{R}$  confluent?

*Proof.* Let  $M = \mathbb{M}(\Sigma, I)$  be a trace monoid and let  $\mathcal{R}$  be a length-reducing TRS over  $M$  that satisfies condition (A). Let  $NF$  be an algorithm that computes an arbitrary normalform  $NF(u, \mathcal{R})$  of a given input trace  $u$  with respect to  $\mathcal{R}$ . Consider the algorithm CONFL in Figure 3. We claim that CONFL outputs “ $\mathcal{R}$  confluent” if and only if  $\mathcal{R}$  is confluent. First we prove that  $\mathcal{R}$  is not confluent if CONFL outputs “ $\mathcal{R}$  not confluent”. If CONFL executes line (\*) then there exist rules  $l_1 \rightarrow r_1$  and  $l_2 \rightarrow r_2$  in  $\mathcal{R}$  and factorizations  $l_1 = p_1 s q_1, l_2 = p_2 s q_2$  such that  $s \neq 1, p_1 I p_2,$  and  $q_1 I q_2$ . Furthermore there exists a normalform  $u_1$  of  $p_1 r_2 q_1$  and a normalform  $u_2$  of  $p_2 r_1 q_2$  such that  $u_1 \neq u_2$ . But then  $\mathcal{R}$  is indeed not confluent since  $p_2 p_1 s q_1 q_2 \rightarrow_{\mathcal{R}} p_2 r_1 q_2 \rightarrow_{\mathcal{R}}^* u_2$  and  $p_2 p_1 s q_1 q_2 = p_1 p_2 s q_2 q_1 \rightarrow_{\mathcal{R}} p_1 r_2 q_1 \rightarrow_{\mathcal{R}}^* u_1$ . Now assume that CONFL executes line (\*\*). Then it holds  $u_1 = u_2 = u$  but there exists an  $a \in \Sigma$  such that either  $a I p_2 s q_1$  or  $a I p_1 s q_2$  and there exist a normalform  $v_1$  of  $au$  and a normalform  $v_2$  of  $ua$  such that  $v_1 \neq v_2$ . Assume that  $a I p_2 s q_1$ . Since  $\mathcal{R}$  satisfies condition

(A2) it follows  $ar_1 = r_1a$  and  $ar_2 = r_2a$ . Hence

$$\begin{aligned} p_2p_1sq_1aq_2 &\rightarrow_{\mathcal{R}} p_2r_1aq_2 = ap_2r_1q_2 \rightarrow_{\mathcal{R}}^* au \rightarrow_{\mathcal{R}}^* v_1 \quad \text{and} \\ p_2p_1sq_1aq_2 &= p_1p_2sq_1aq_2 = p_1ap_2sq_2q_1 \rightarrow_{\mathcal{R}} p_1ar_2q_1 = p_1r_2q_1a \rightarrow_{\mathcal{R}}^* ua \rightarrow_{\mathcal{R}}^* v_2. \end{aligned}$$

Thus, again  $\mathcal{R}$  is not confluent. The case that  $aI p_1sq_2$  can be dealt similarly by considering the trace  $p_2ap_1sq_1q_2$  instead of  $p_2p_1sq_1aq_2$ .

Now assume that CONFL outputs “ $\mathcal{R}$  confluent” in line (\*\*\*). We have to show that  $\mathcal{R}$  is confluent. By induction on the length of traces it suffices to prove the following implication:

If  $\mathcal{R}$  is confluent on all traces  $t'$  with  $|t'| < |t|$  then  $\mathcal{R}$  is confluent on  $t$ .

Thus, let  $t \in M$  and assume that  $\mathcal{R}$  is confluent on all traces  $t'$  with  $|t'| < |t|$ . We have to prove that all pairs  $(t_1, t_2)$  such that  $t \rightarrow_{\mathcal{R}}^i t_1$  and  $t \rightarrow_{\mathcal{R}}^j t_2$  for some  $i, j \geq 0$  are confluent. Of course the case  $i = 0$  or  $j = 0$  is trivial. Let us assume for a moment that we have already considered all cases with  $i = 1 = j$ . Then we can apply the same arguments as in the (standard) proof of Newman’s lemma:  $t \rightarrow_{\mathcal{R}} s_1 \rightarrow_{\mathcal{R}}^* t_1$  and  $t \rightarrow_{\mathcal{R}} s_2 \rightarrow_{\mathcal{R}}^* t_2$  imply that there exists a trace  $s$  with  $s_i \rightarrow_{\mathcal{R}}^* s$  ( $i \in \{1, 2\}$ ). Since  $|s_1| < |t|$  and  $s_1 \rightarrow_{\mathcal{R}}^* t_1$ ,  $s_1 \rightarrow_{\mathcal{R}}^* s$  it holds  $t_1 \rightarrow_{\mathcal{R}}^* u$  and  $s \rightarrow_{\mathcal{R}}^* u$  for some trace  $u$ . Since also  $|s_2| < |t|$  and  $s_2 \rightarrow_{\mathcal{R}}^* t_2$ ,  $s_2 \rightarrow_{\mathcal{R}}^* s \rightarrow_{\mathcal{R}}^* u$  it holds  $t_2 \rightarrow_{\mathcal{R}}^* v$  and  $u \rightarrow_{\mathcal{R}}^* v$ , i.e.,  $t_1 \rightarrow_{\mathcal{R}}^* u \rightarrow_{\mathcal{R}}^* v$  for some trace  $v$ .

Thus, it suffices to consider arbitrary factorizations  $t = u_1l_1v_1 = u_2l_2v_2$  where  $(l_1, r_1), (l_2, r_2) \in \mathcal{R}$ . We have to prove that the pair  $(u_1r_1v_1, u_2r_2v_2)$  is confluent. Lemma 2.1 applied to the identity  $u_1l_1v_1 = u_2l_2v_2$  gives nine traces  $y_i, p_i, q_i$  ( $i \in \{1, 2\}$ ) and  $s$  such that (see also the diagram below)

- $l_1 = p_1sq_1, \quad l_2 = p_2sq_2,$
- $u_1 = y_1p_2w_2, \quad u_2 = y_1p_1w_1,$
- $v_1 = w_1q_2y_2, \quad v_2 = w_2q_1y_2,$
- $t = y_1p_1w_1p_2sq_2w_2q_1y_2 = y_1p_2w_2p_1sq_1w_1q_2y_2,$
- $p_1I p_2, \quad q_1I q_2, \quad w_1I p_2sw_2q_1, \quad w_2I p_1w_1sq_2.$

$v_2$	$w_2$	$q_1$	$y_2$
$l_2$	$p_2$	$s$	$q_2$
$u_2$	$y_1$	$p_1$	$w_1$
$u_1$	$l_1$	$v_1$	

We have to show that the pair  $(y_1p_1w_1r_2w_2q_1y_2, y_1p_2w_2r_1w_1q_2y_2)$  is confluent. First assume that either  $y_1 \neq 1$  or  $y_2 \neq 1$ . For the trace  $t' = p_1w_1p_2sq_2w_2q_1 = p_2w_2p_1sq_1w_1q_2$  it holds  $|t'| < |t|$  and

$$t' = p_1w_1l_2w_2q_1 \rightarrow_{\mathcal{R}} p_1w_1r_2w_2q_1, \quad t' = p_2w_2l_1w_1q_2 \rightarrow_{\mathcal{R}} p_2w_2r_1w_1q_2.$$

Thus the pair  $(p_1w_1r_2w_2q_1, p_2w_2r_1w_1q_2)$  is confluent. But then the same also holds for the pair  $(y_1p_1w_1r_2w_2q_1y_2, y_1p_2w_2r_1w_1q_2y_2)$ . Thus we may assume that  $y_1 = y_2 = 1$  and we have to consider the pair  $(p_1w_1r_2w_2q_1, p_2w_2r_1w_1q_2)$ .

Next assume that  $s = 1$ , i.e.,  $l_1 = p_1q_1$  and  $l_2 = p_2q_2$ . First assume that also  $p_1 = 1$ , i.e.,  $l_1 = q_1$ . We have to show that the pair  $(w_1r_2w_2q_1, p_2w_2r_1w_1q_2)$  is

confluent. Since  $w_1 r_2 w_2 q_1 = w_1 r_2 w_2 l_1 \rightarrow_{\mathcal{R}} w_1 r_2 w_2 r_1$  it suffices to prove that also  $p_2 w_2 r_1 w_1 q_2 \rightarrow_{\mathcal{R}} w_1 r_2 w_2 r_1$ . This can be deduced as follows: Since  $q_1 I w_1 q_2$ , i.e.,  $l_1 I w_1 q_2$ , condition (A2) (more precisely the remark after condition (A2)) for  $\mathcal{R}$  implies  $w_1 r_1 = r_1 w_1$  and  $q_2 r_1 = r_1 q_2$ . Thus

$$\begin{aligned} p_2 w_2 r_1 w_1 q_2 &= p_2 w_2 w_1 q_2 r_1 && (\text{since } r_1 w_1 q_2 = w_1 q_2 r_1) \\ &= w_1 p_2 q_2 w_2 r_1 && (\text{since } w_1 I w_2, w_1 I p_2, \text{ and } w_2 I q_2) \\ &\rightarrow_{\mathcal{R}} w_1 r_2 w_2 r_1 \end{aligned}$$

Thus, we may assume that  $p_1 \neq 1$ . Similarly we may assume that also  $q_1 \neq 1$ ,  $p_2 \neq 1$ , and  $q_2 \neq 1$ . But then condition (A1) implies that there exist factorizations  $r_1 = s_1 t_1$ ,  $r_2 = s_2 t_2$  such that  $a I p_i$  implies  $a I s_i$  and  $a I q_i$  implies  $a I t_i$  for all  $a \in \Sigma$ . In particular it holds

$$p_2 I s_1, w_2 I s_1, p_1 I s_2, w_1 I s_2, q_2 I t_1, w_1 I t_1, q_1 I t_2, w_2 I t_2.$$

Furthermore  $p_2 I s_1$  implies  $s_2 I s_1$  and  $q_2 I t_1$  implies  $t_2 I t_1$ . Thus, we obtain

$$\begin{aligned} p_2 w_2 r_1 w_1 q_2 &= p_2 w_2 s_1 t_1 w_1 q_2 = s_1 w_1 p_2 q_2 w_2 t_1 \rightarrow_{\mathcal{R}} s_1 w_1 s_2 t_2 w_2 t_1 = s_2 w_2 s_1 t_1 w_1 t_2, \\ p_1 w_1 r_2 w_2 q_1 &= p_1 w_1 s_2 t_2 w_2 q_1 = s_2 w_2 p_1 q_1 w_1 t_2 \rightarrow_{\mathcal{R}} s_2 w_2 s_1 t_1 w_1 t_2. \end{aligned}$$

In the rest of the proof we assume that  $s \neq 1$ . But then we have one of the situations that are considered in the two outermost **forall**-loops of CONFL. Since we assume that CONFL outputs “ $\mathcal{R}$  confluent” we know that there exists a trace  $u$  such that  $p_1 r_2 q_1 \rightarrow_{\mathcal{R}}^* u$  and  $p_2 r_1 q_2 \rightarrow_{\mathcal{R}}^* u$ . Furthermore since  $\mathcal{R}$  satisfies condition (A2) and  $s I w_1 w_2$  it holds  $r_i w_j = w_j r_i$  for  $i, j \in \{1, 2\}$ . Hence  $p_1 w_1 r_2 w_2 q_1 = w_2 p_1 r_2 q_1 w_1 \rightarrow_{\mathcal{R}}^* w_2 u w_1$  and  $p_2 w_2 r_1 w_1 q_2 = w_1 p_2 r_1 q_2 w_2 \rightarrow_{\mathcal{R}}^* w_1 u w_2$  and it suffices to prove that the pair  $(w_2 u w_1, w_1 u w_2)$  is confluent. The case  $w_1 = 1 = w_2$  is trivial. Thus assume w.l.o.g.  $w_1 = wa$ , where  $a \in \Sigma$ . Since  $w_1 I p_2 s w_2 q_1$  it follows  $a I p_2 s q_1$ . Thus  $a \in \Sigma$  is one of the symbols that are considered in the innermost **forall**-loop of CONFL. It follows that there exists a trace  $v$  such that  $au \rightarrow_{\mathcal{R}}^* v$  and  $ua \rightarrow_{\mathcal{R}}^* v$ . Thus

$$wuaw_2 \rightarrow_{\mathcal{R}}^* v w v w_2 \quad \text{and} \quad w_1 u w_2 = w a u w_2 \rightarrow_{\mathcal{R}}^* v w v w_2. \quad (2)$$

Next let us consider the trace  $t' = p_1 w p_2 s q_2 w_2 q_1 = p_1 w l_2 w_2 q_1$  ( $t'$  results from  $t$  by replacing the factor  $w_1 = wa$  by  $w$ ). It holds  $|t'| < |t|$  and since  $w$  satisfies the same independencies as  $w_1$  it holds  $t' = p_2 w_2 p_1 s q_1 w q_2 = p_2 w_2 l_1 w q_2$ . Thus we obtain (note that  $w r_1 = r_1 w$  and  $w r_2 = r_2 w$ )

$$\begin{aligned} t' &\rightarrow_{\mathcal{R}} p_1 w r_2 w_2 q_1 = w_2 p_1 r_2 q_1 w \rightarrow_{\mathcal{R}}^* w_2 u w \quad \text{and} \\ t' &\rightarrow_{\mathcal{R}} p_2 w_2 r_1 w q_2 = w p_2 r_1 q_2 w_2 \rightarrow_{\mathcal{R}}^* w u w_2. \end{aligned}$$

Hence there exists a trace  $x$  such that  $w_2 u w \rightarrow_{\mathcal{R}}^* x$  and  $w u w_2 \rightarrow_{\mathcal{R}}^* x$ . It follows

$$w_2 u w_1 = w_2 u w a \rightarrow_{\mathcal{R}}^* x a \quad \text{and} \quad w u a w_2 = w u w_2 a \rightarrow_{\mathcal{R}}^* x a. \quad (3)$$

Finally since  $wuaw_2 \rightarrow_{\mathcal{R}}^* wvw_2$  by (2) and  $wuaw_2 \rightarrow_{\mathcal{R}}^* xa$  by (3) and  $|wuaw_2| = |w_1uw_2| \leq |w_1p_1r_2q_1w_2| < |p_1w_1p_2sq_2w_2q_1| = |t|$  (where the strict inequality follows from  $|r_2| < |p_2sq_2|$ ) there exists a trace  $z$  such that  $wvw_2 \rightarrow_{\mathcal{R}}^* z$  and  $xa \rightarrow_{\mathcal{R}}^* z$ . Now we obtain  $w_1uw_2 \rightarrow_{\mathcal{R}}^* wvw_2 \rightarrow_{\mathcal{R}}^* z$  from (2) and  $w_2uw_1 \rightarrow_{\mathcal{R}}^* xa \rightarrow_{\mathcal{R}}^* z$  from (3). Thus the pair  $(w_1uw_2, w_2uw_1)$  is confluent and the correctness of CONFL is proved.  $\square$

**Theorem 5.2.**  $\text{COSP}(M)$  is in P for every trace monoid  $M$ .

*Proof.* For special VRSs we already proved the statement of the theorem. On the other hand if  $I \neq (\Sigma \times \Sigma) \setminus \text{Id}_{\Sigma}$  then CONFL runs in polynomial time. This follows from the following two facts: (i) For a fixed independence alphabet  $(\Sigma, I)$ , the number of different factorizations  $l = psq$  of a trace  $l$  is bounded by a polynomial in the length of  $|l|$ . This follows from the fact that the number of prefixes of a trace  $t$  is bounded by a polynomial in  $|t|$  [BMS89]. (ii) A normalform of a trace  $t$  with respect to a length-reducing TRS  $\mathcal{R}$ , which is not a VRS, can be calculated in time bounded by a polynomial in  $|t|$  and  $\|\mathcal{R}\|$ , see [Die90c, Die90a, BD95, Ber95, BD96] for the normalform problem <sup>1</sup>.  $\square$

One might further ask, whether confluence can be decided for arbitrary monadic TRSs. We leave this as an open question.

We close this section with a simple problem that is decidable for monadic STSs but in general undecidable for special TRSs. A trace  $u \in \mathbb{M}(\Sigma, I)$  is said to be *connected* if there does not exist a factorization  $u = vw$  such that  $v \neq 1 \neq w$  and  $vIw$ . A set  $L \subseteq \mathbb{M}(\Sigma, I)$  is connected if every trace in  $L$  is connected. A set  $L \subseteq \mathbb{M}(\Sigma, I)$  is *recognizable* if the set  $\{s \in \Sigma^* \mid \exists u \in L : u = [s]_I\}$  of all words that represent a trace in  $L$  is recognizable. This is just one of several different possibilities of defining recognizable trace languages, see e.g. chapter 6 of [DR95]. A fundamental result of Ochmański [Och85], states that the class of all recognizable trace languages in  $\mathbb{M}(\Sigma, I)$  is the smallest class  $\mathcal{C}$  that contains all singleton subsets of  $\mathbb{M}(\Sigma, I)$  and that is closed under (i) union, (ii) concatenation of two languages (where the concatenation of  $L_1$  and  $L_2$  is  $L_1L_2 = \{u_1u_2 \mid u_1 \in L_1, u_2 \in L_2\}$ ) and (iii) the star-operator restricted to connected languages, i.e., if  $L \in \mathcal{C}$  is connected then also  $L^* = \{u_1u_2 \cdots u_n \mid n \geq 0, u_1, u_2, \dots, u_n \in L\} \in \mathcal{C}$ . Given a TRS  $\mathcal{R}$  over  $M$  and a set  $L \subseteq M$  we denote by  $\Delta_{\mathcal{R}}^*(L) = \{v \in M \mid \exists u \in L : u \rightarrow_{\mathcal{R}}^* v\}$  the set of all *descendants* of  $L$  with respect to  $\mathcal{R}$ . It is known that if  $L \subseteq \Sigma^*$  is a recognizable word language and  $\mathcal{R}$  is a monadic STS then also  $\Delta_{\mathcal{R}}^*(L)$  is recognizable [BO85]. But already for special TRSs that contain only one rule this fact does not hold in general, as the following example shows.

**Example 5.3.** Let  $\Sigma = \{a, b, c\}$  and  $I = \{(a, c), (c, a)\}$ . Since the trace  $u = [abc]_I$  is connected, the language  $\{u\}^*$  is recognizable. Let  $\mathcal{R}$  be the special TRS  $\{b \rightarrow 1\}$ . Assume that  $\Delta_{\mathcal{R}}^*(\{u\}^*)$  is recognizable. Since recognizable trace languages are closed under intersection, also the language  $\Delta_{\mathcal{R}}^*(\{u\}^*) \cap \{a, c\}^* =$

<sup>1</sup>The algorithms in [Die90c, Die90a, BD95, Ber95, BD96] are all non uniform, i.e., the TRSs is fixed. But it is easy to see that they run also in the uniform case in polynomial time.

$\{[a^n c^n]_I \mid n \geq 0\}$  would be recognizable. But this is not the case, see e.g. [DR95], pp 172.

For a class  $\mathcal{C}$  of TRSs over a trace monoid  $M$  we define the *extended word problem* for  $\mathcal{C}$  and  $M$  as follows [BO85]:

INPUT: A TRS  $\mathcal{R} \in \mathcal{C}$  and two recognizable languages  $L_1$  and  $L_2$  of  $M$ .

QUESTION: Do there exist  $u_1 \in L_1$  and  $u_2 \in L_2$  such that  $u_1 \leftrightarrow_{\mathcal{R}}^* u_2$ ?

A simple consequence of the above mentioned closure of recognizable word languages under the operator  $\Delta_{\mathcal{R}}^*$  for a monadic STS  $\mathcal{R}$  is that the extended word problem for monadic and confluent STSs is decidable [BO85]. In contrast to this, the following theorem holds.

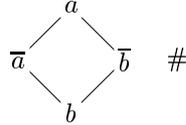

**Theorem 5.4.** There exists a trace monoid  $M = \mathbb{M}(\Sigma, I)$ , a special TRS  $\mathcal{R}$  over  $M$  of the form  $\mathcal{R} = \{a \rightarrow 1\}$ , where  $a \in \Sigma$ , and a recognizable language  $L_1 \subseteq M$  such that the following problem is undecidable.

INPUT: A recognizable language  $L_2 \subseteq M$ .

QUESTION: Do there exist  $u_1 \in L_1$  and  $u_2 \in L_2$  such that  $u_1 \leftrightarrow_{\mathcal{R}}^* u_2$ ?

*Proof.* It is well-known that the Post Correspondence Problem, briefly PCP, is undecidable over a two-element alphabet. Furthermore it can be required that every solution of the PCP has to start with a distinguished pair. Thus the following problem is undecidable, which is called the modified PCP over  $\{a, b\}$ :  
 INPUT: A set  $\{(s_1, t_1), \dots, (s_n, t_n)\}$  of pairs with  $s_i, t_i \in \{a, b\}^*$  for  $1 \leq i \leq n$ .  
 QUESTION: Does there exist a  $i_1 i_2 \dots i_k \in \{1, \dots, n\}^*$  with  $s_1 s_{i_1} s_{i_2} \dots s_{i_k} = t_1 t_{i_1} t_{i_2} \dots t_{i_k}$ ?

Let  $P = \{(s_1, t_1), \dots, (s_n, t_n)\}$  be an instance of the modified PCP over  $\{a, b\}$ . Let  $\{\bar{a}, \bar{b}\}$  be a copy of  $\{a, b\}$  and let  $\#$  be an additional symbol. Let  $\Sigma = \{a, b, \bar{a}, \bar{b}, \#\}$  and define an independence relation  $I$  on  $\Sigma$  by the following graph:

Thus the symbols in  $\{a, b\}$  and  $\{\bar{a}, \bar{b}\}$  pairwise commute whereas  $\#$  is dependent from all symbols. For a word  $s \in \{a, b\}^*$  the word  $\bar{s}$  is defined in the obvious way. Let  $L_1 = \{[a\#\bar{a}]_I, [b\#\bar{b}]_I\}^*$  and  $L_2 = \{[s_1\#\bar{t}_1]_I\} \{[s_i\#\bar{t}_i]_I \mid 1 \leq i \leq n\}^*$ . By Ochmański's theorem both  $L_1$  and  $L_2$  are recognizable subsets of  $\mathbb{M}(\Sigma, I)$ . Let  $\mathcal{R} = \{\# \rightarrow 1\}$ . Thus  $\mathcal{R}$  is special and confluent. Now the PCP  $P$  has a solution if and only if

$$\exists u_1 \in L_1, u_2 \in L_2, v \in IRR(\mathcal{R}) : u_1 \rightarrow_{\mathcal{R}}^* v, u_2 \rightarrow_{\mathcal{R}}^* v \quad \text{if and only if}$$

$$\exists u_1 \in L_1, u_2 \in L_2, v \in \mathbb{M}(\Sigma, I) : u_1 \rightarrow_{\mathcal{R}}^* v, u_2 \rightarrow_{\mathcal{R}}^* v \quad \text{if and only if}$$

$$\exists u_1 \in L_1, u_2 \in L_2 : u_1 \leftrightarrow_{\mathcal{R}}^* u_2$$

where the last equivalence holds since  $\mathcal{R}$  is confluent. □

It might be an interesting problem to characterize those trace monoids for which the extended word problem for confluent and monadic (or special) TRSs is decidable.

## 6 Conclusion

In this paper we have investigated the complexity of the confluence problem for restricted kinds of semi-Thue systems, vector replacement systems and general trace rewriting systems. We would like to close this paper with a list several questions that remain unsolved.

- What is the complexity of the confluence problem for length-reducing vector replacement system if the dimension is fixed? Note that in Theorem 4.1, the dimension is not fixed.
- Are the upper bounds given in Theorem 4.3, Theorem 4.4 and Theorem 5.2 sharp, i.e., are the decision problems, considered in these theorems, also hard for the given complexity classes?
- Is confluence decidable for general monadic trace rewriting systems. This question was already asked in [Die90b]?
